

Renewables help us to reach net zero emissions

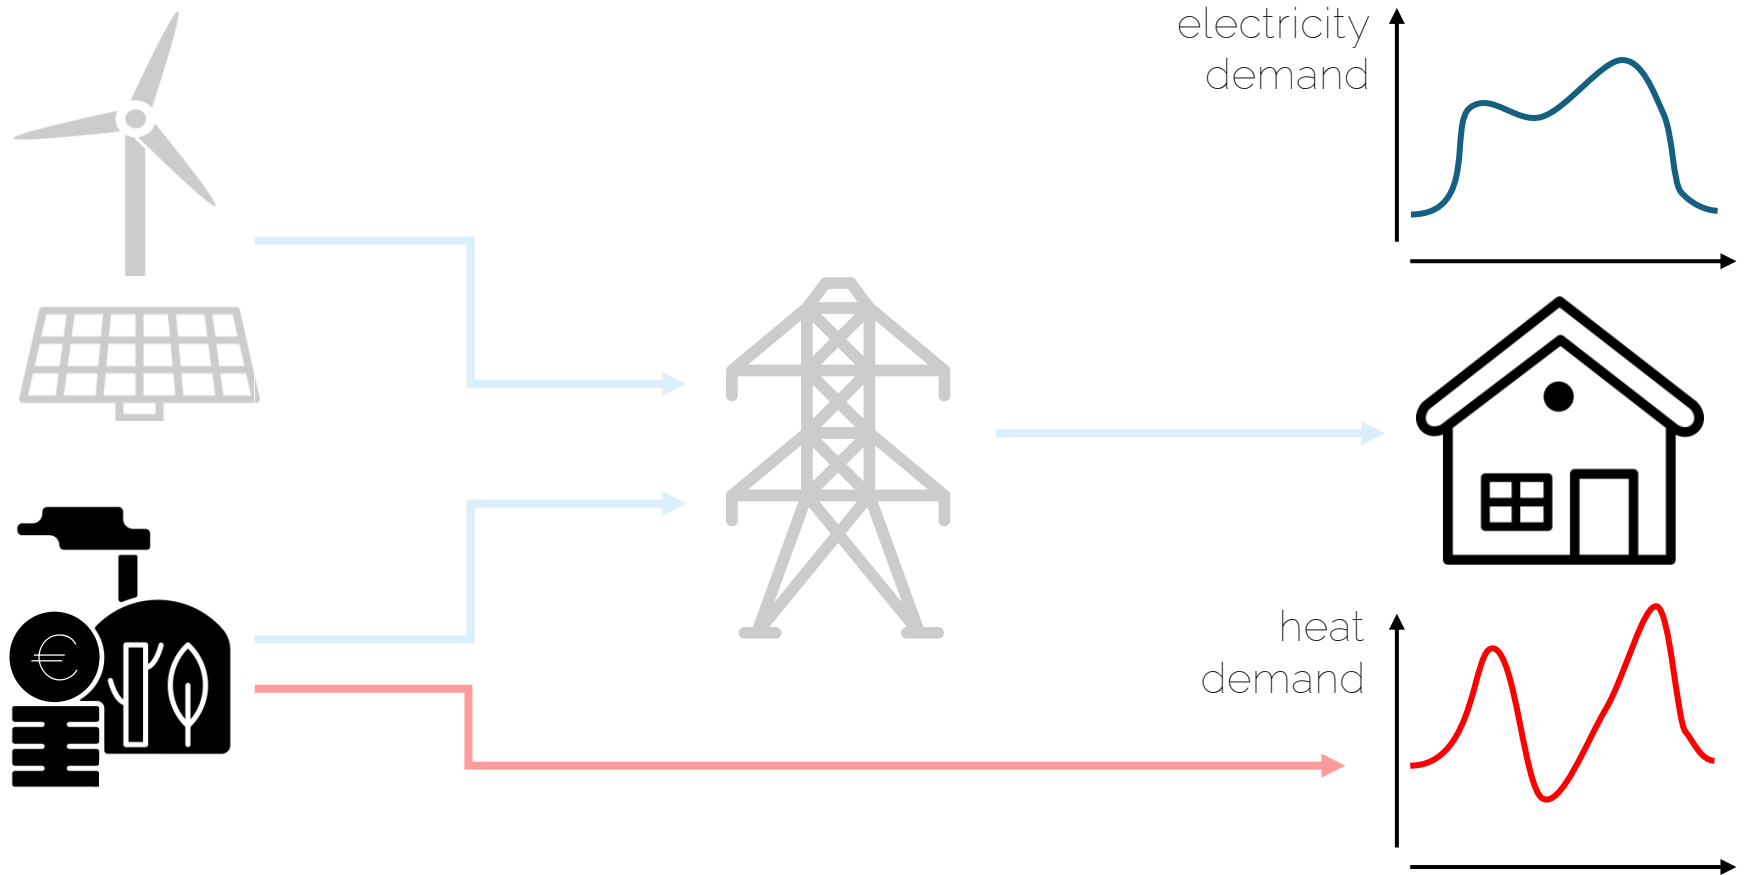

Transition towards net zero emissions is hindered by **uncertainties**

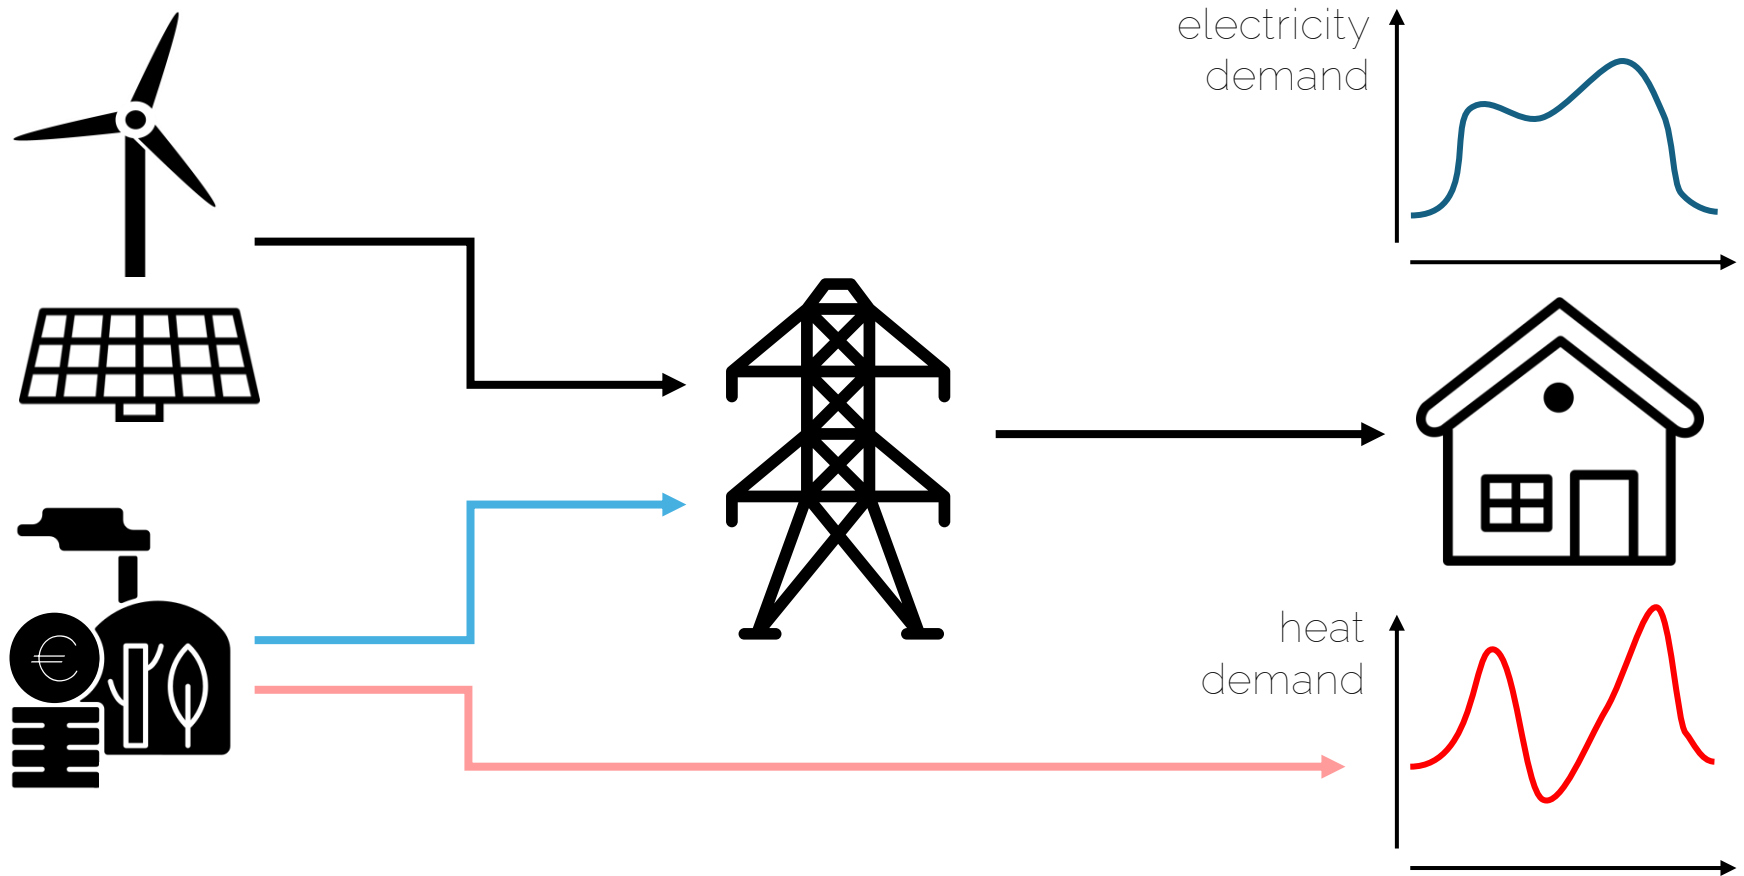

Transition towards net zero emissions induces the need for flexible power generation

Combined heat and power plants can satisfy the heat demand of local buyers

Combined heat and power plant provide flexibility in electric and heat networks

FLEX-CHP

The contribution of biomass- and waste-fired CHP's
to the security of supply and the stability
of the electrical grid in Belgium

General philosophy: "we need to use less and recycle more, as the best waste is no waste"

How much biomass and waste will there be available in the future in Belgium?

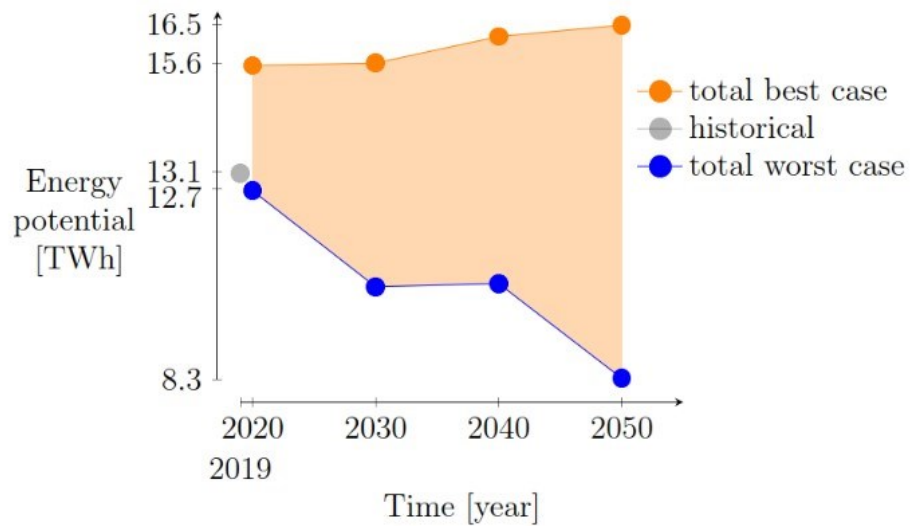

How much biomass and waste will there be available in the future in Belgium?

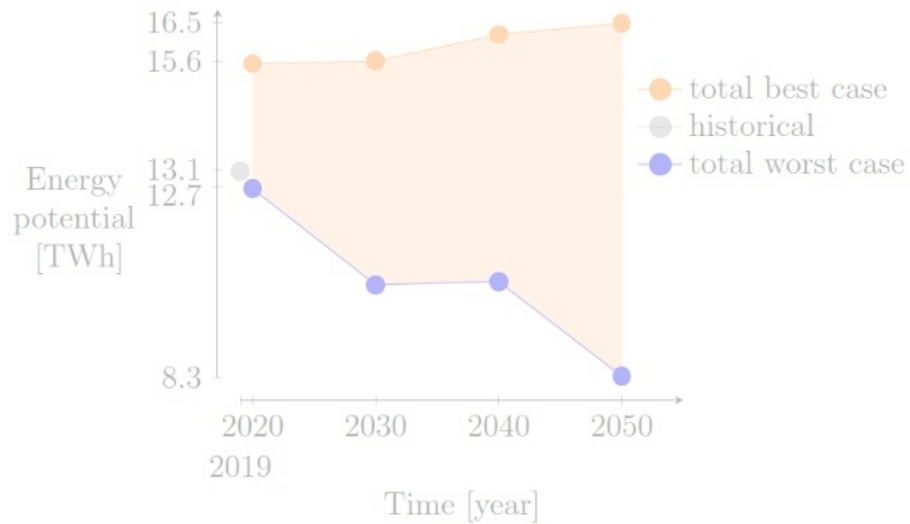

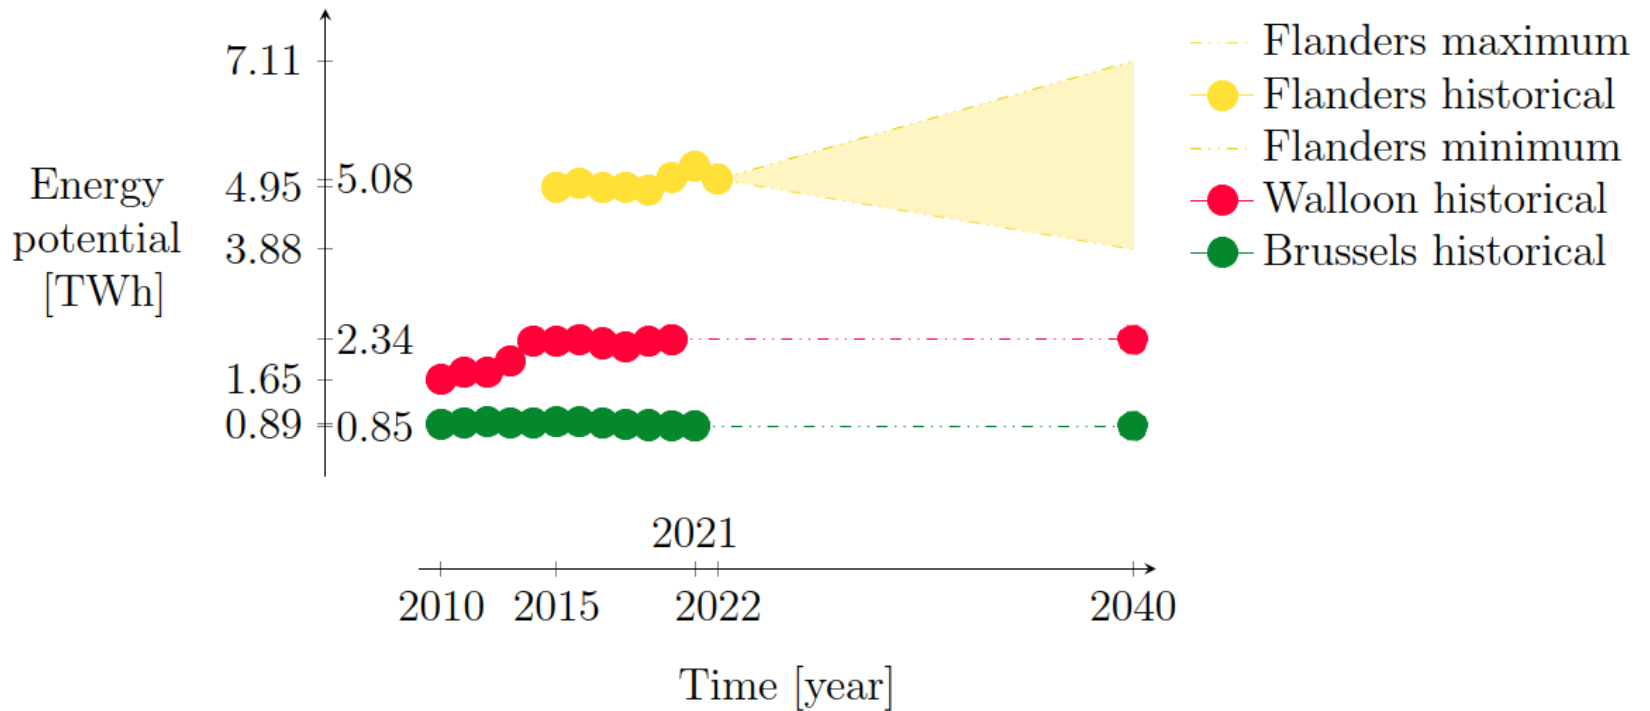

How much biomass and waste will there be available in the future in Belgium?

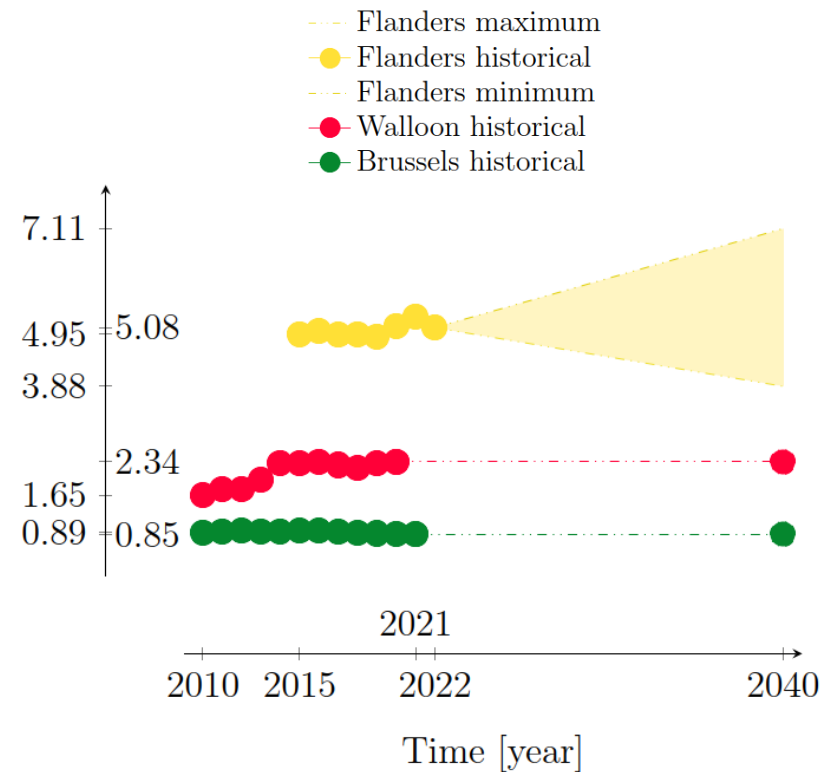

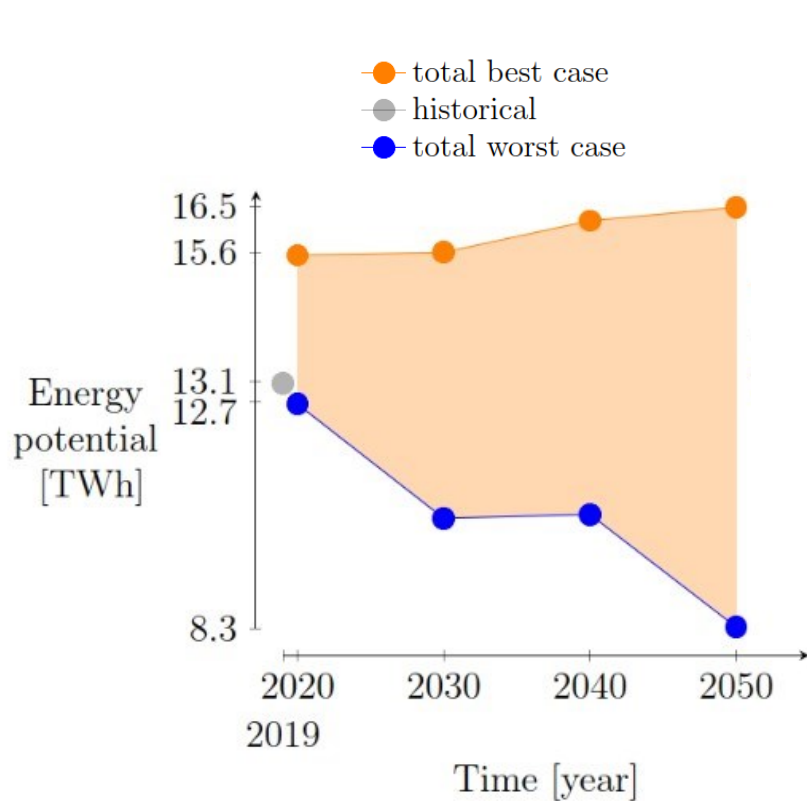

How much biomass and waste will there be available in the future in Belgium?

BWtE created two scenarios for Flanders, while for Wallonia and Brussels this is not possible now

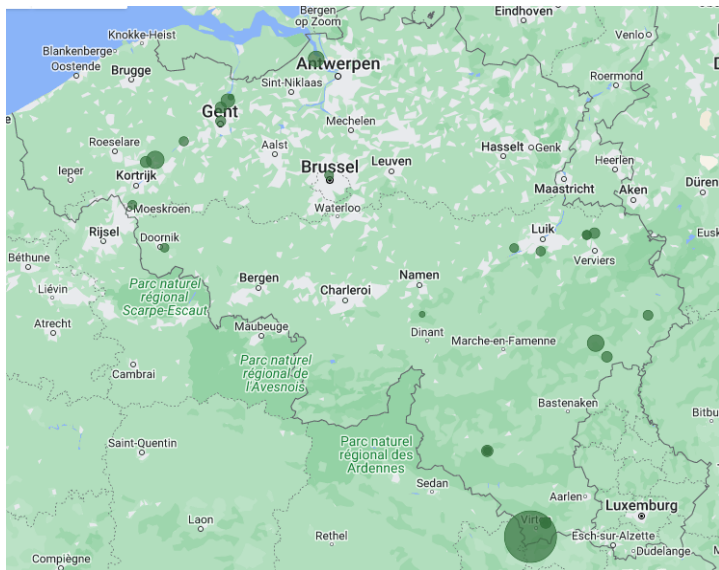

An uncertain biomass and waste potential in the future in Belgium

What if there is a decrease in energy potential?

What if there is a decrease in energy potential?

Biomass-fueled cogeneration

Municipal waste-fueled cogeneration

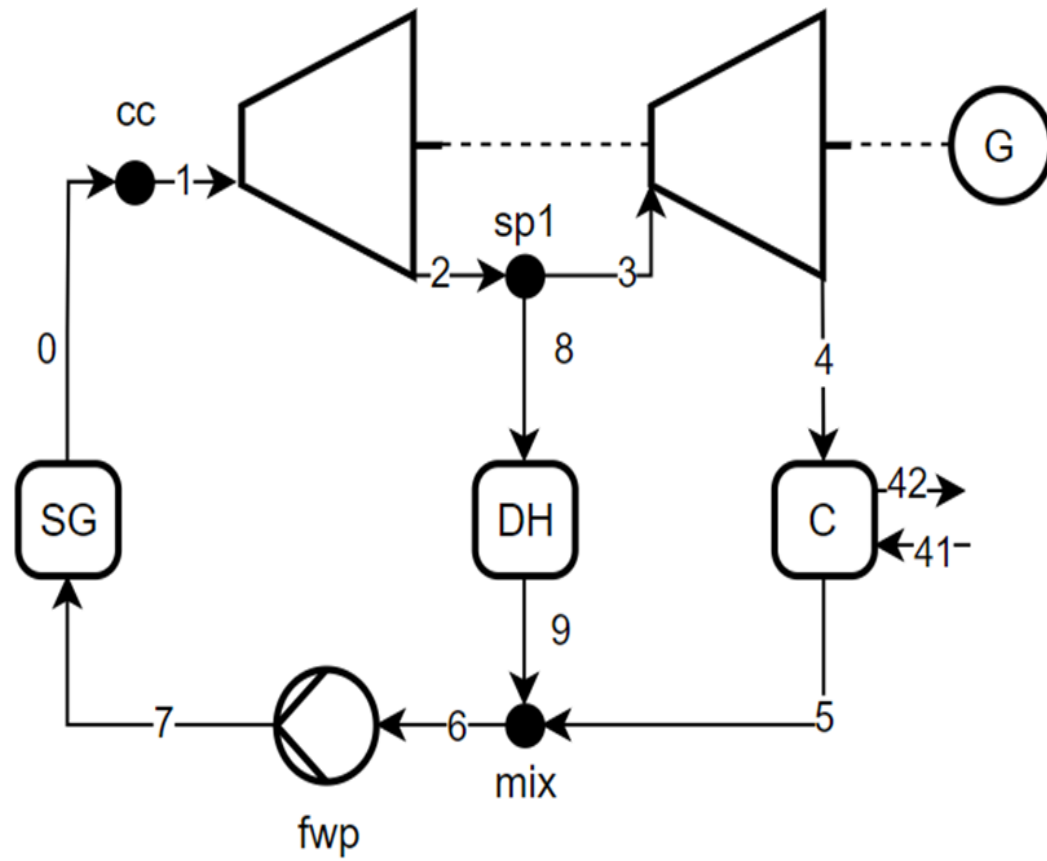

Most likely scenario is the shutdown of some plants

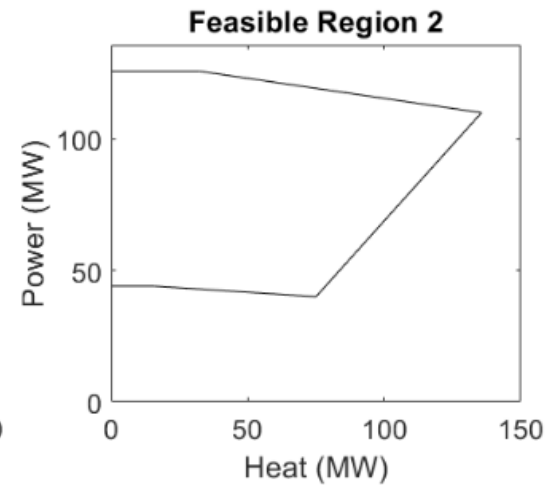

With a reduction in fuel availability,
there is room for flexibility

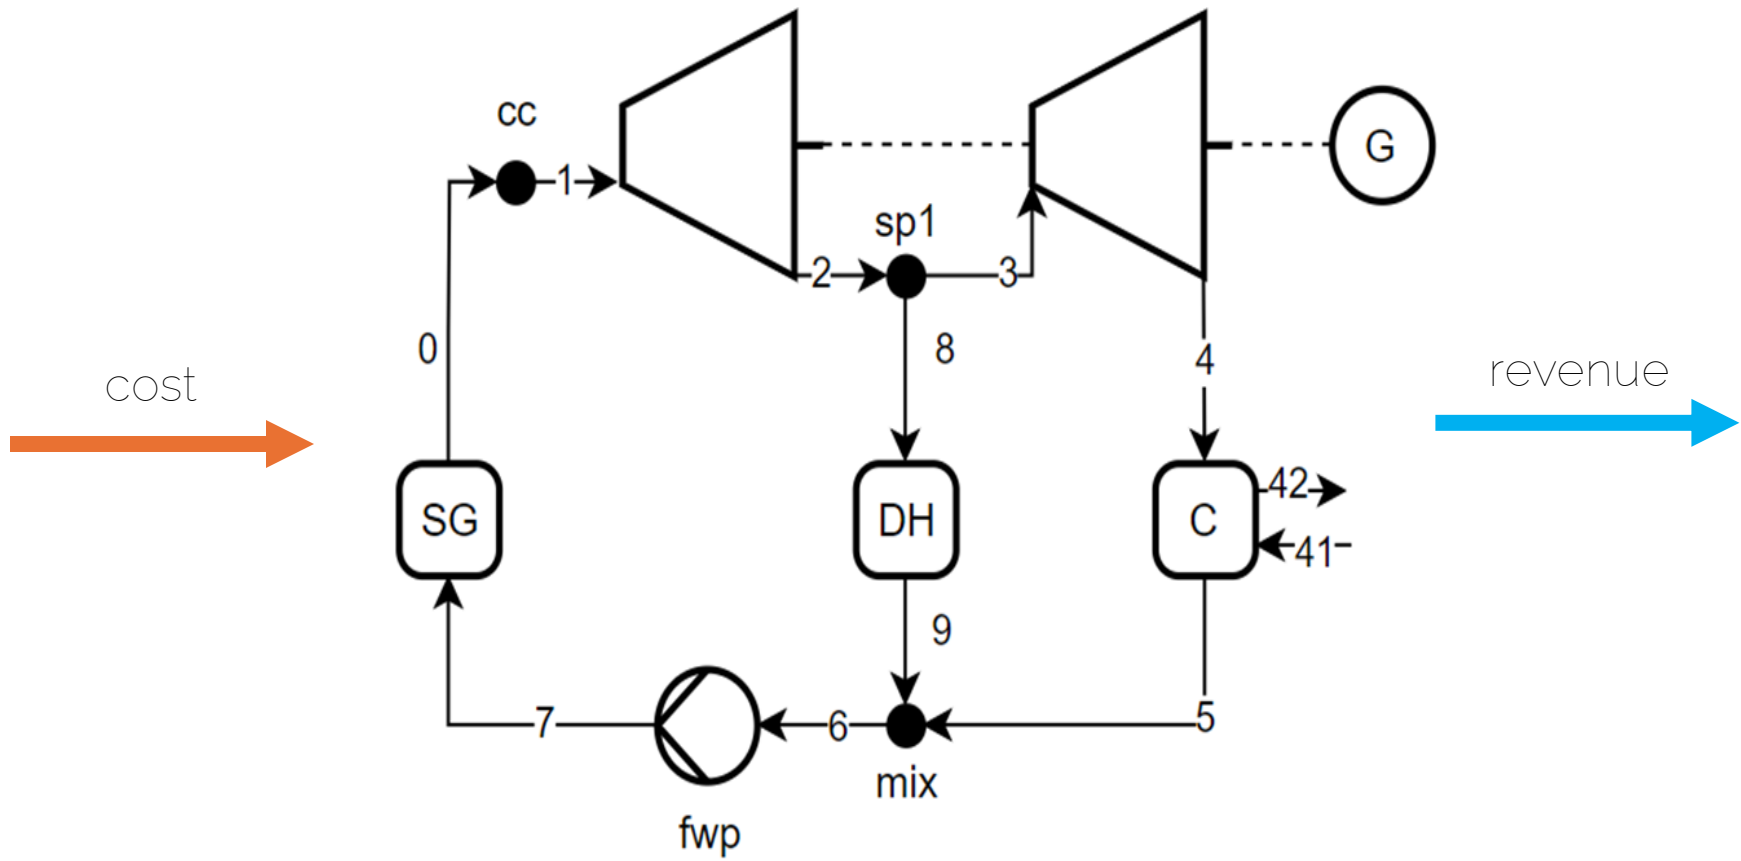

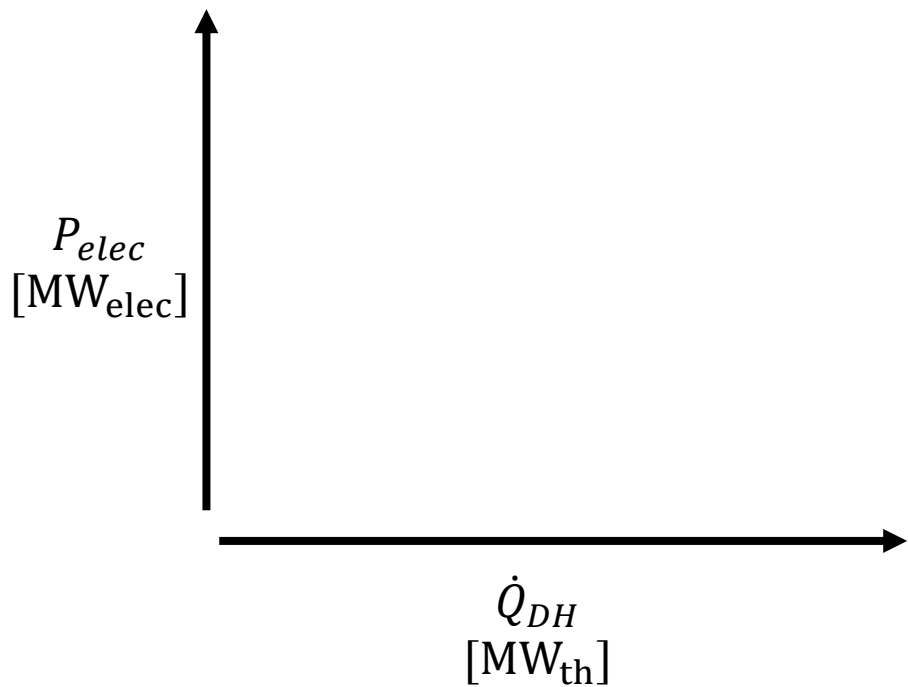

From next-kraftwerke

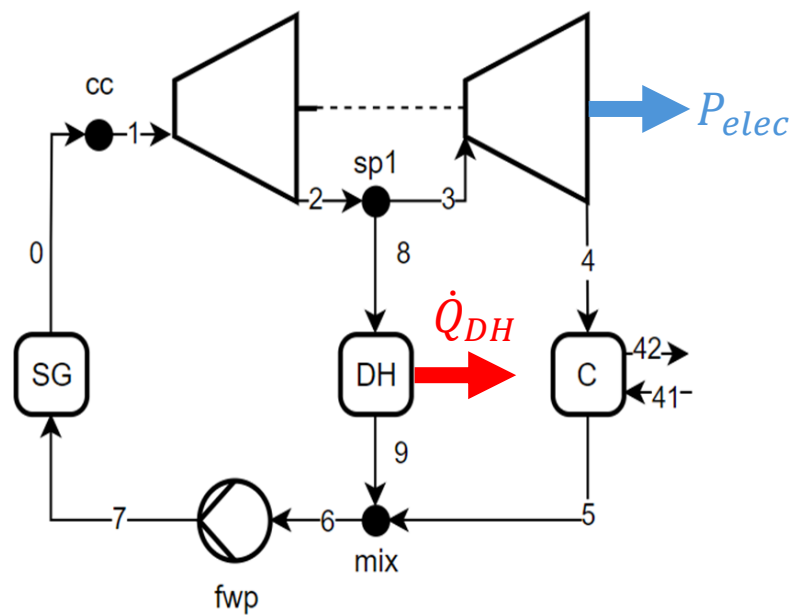

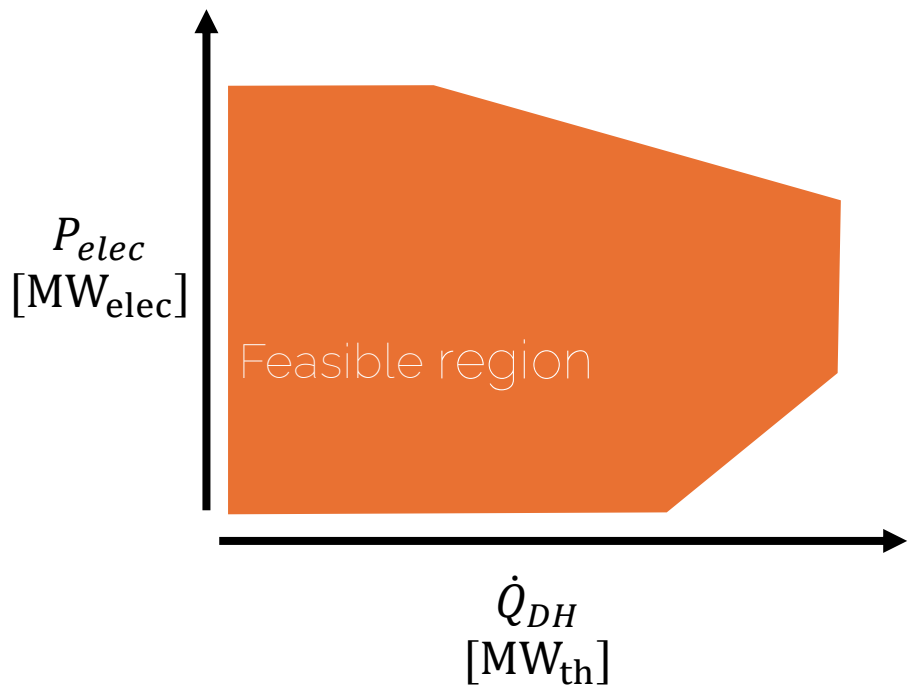

Every cogeneration plant has a unique feasible region

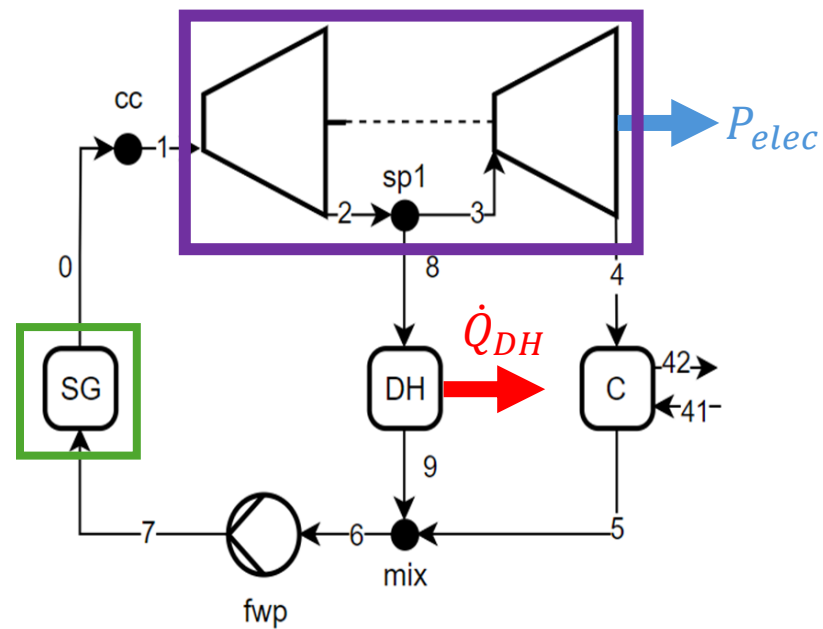

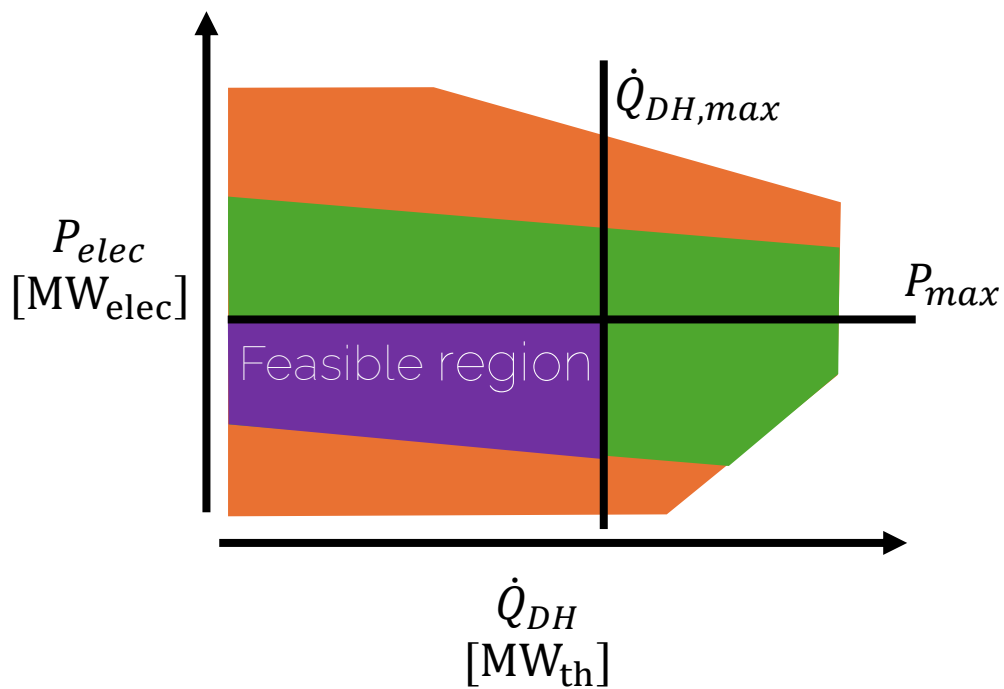

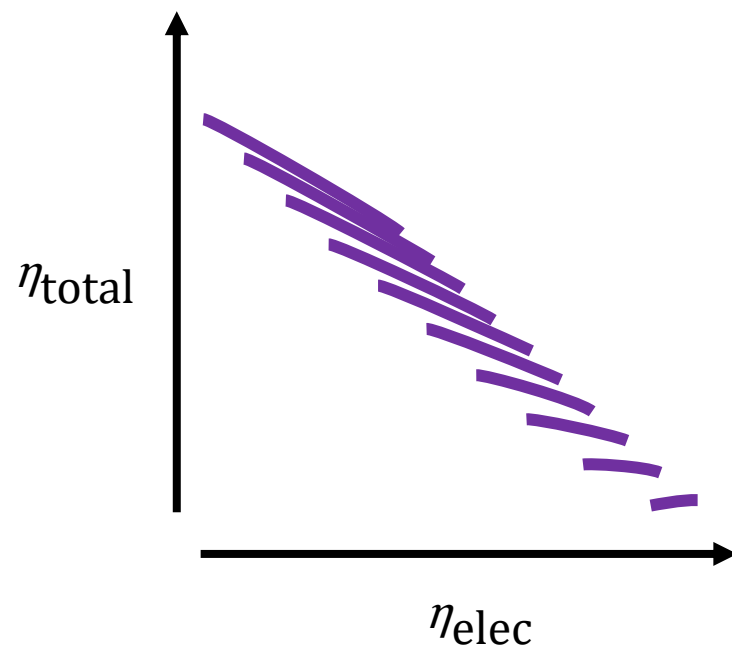

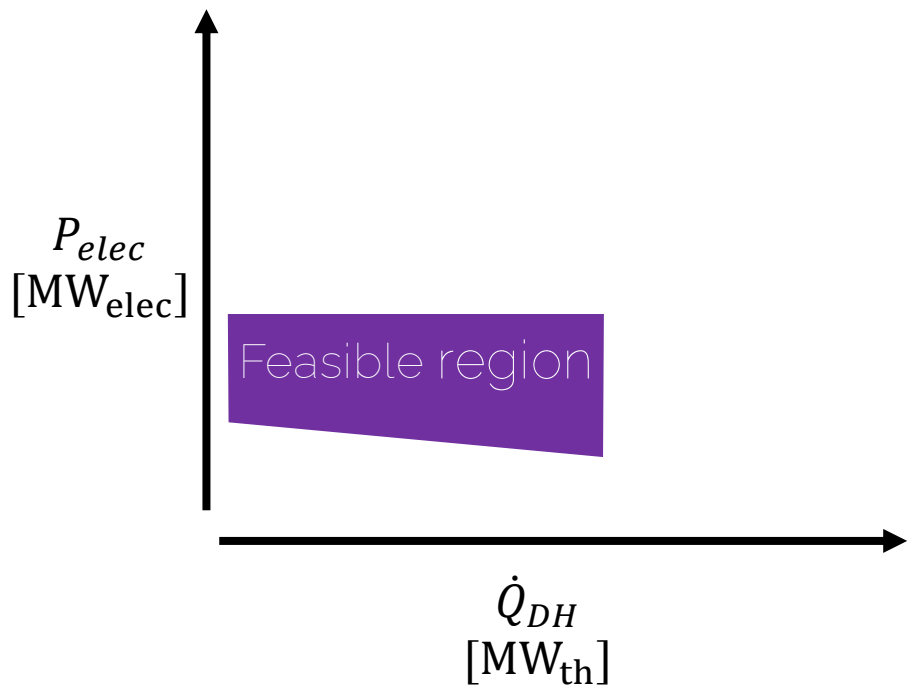

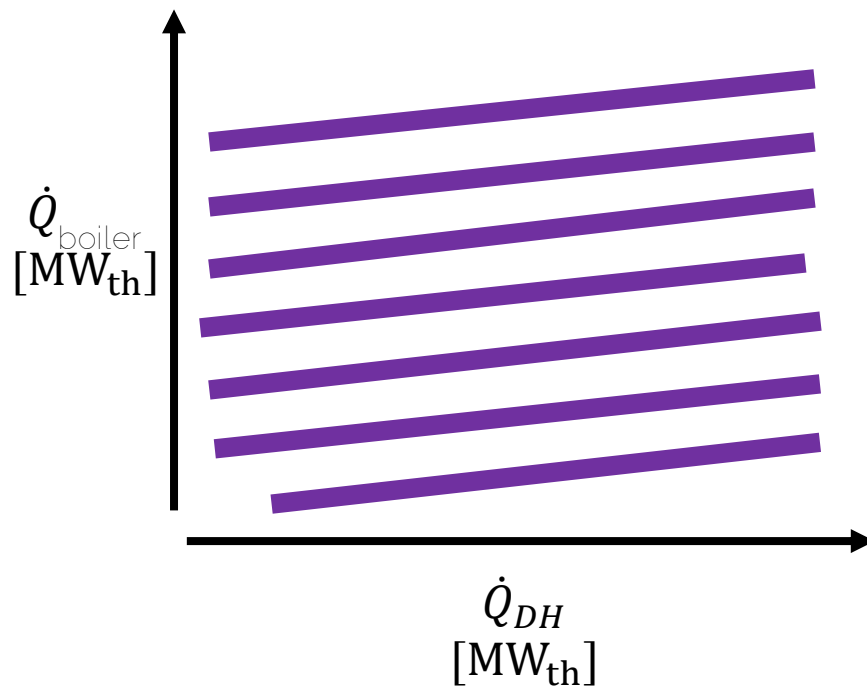

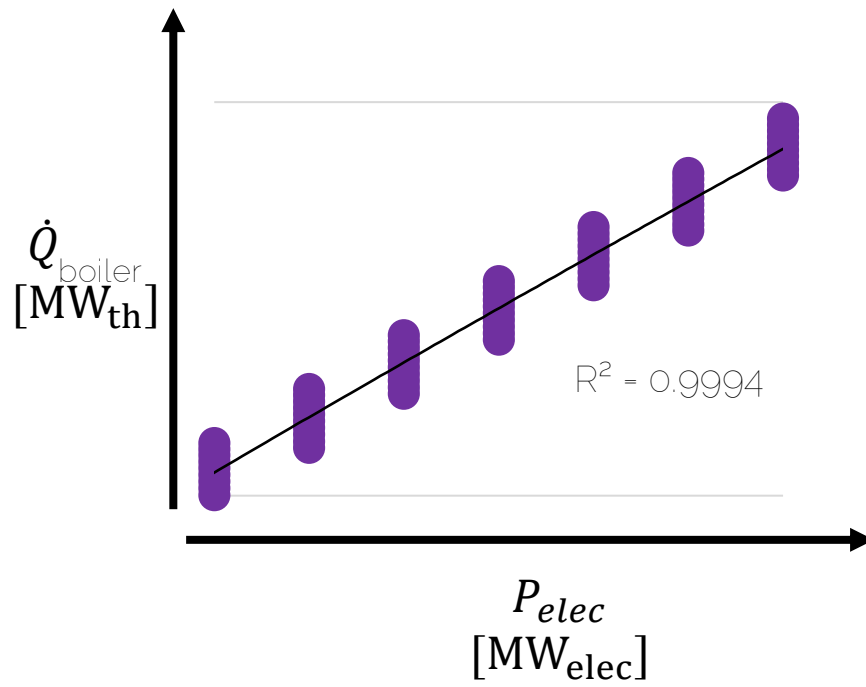

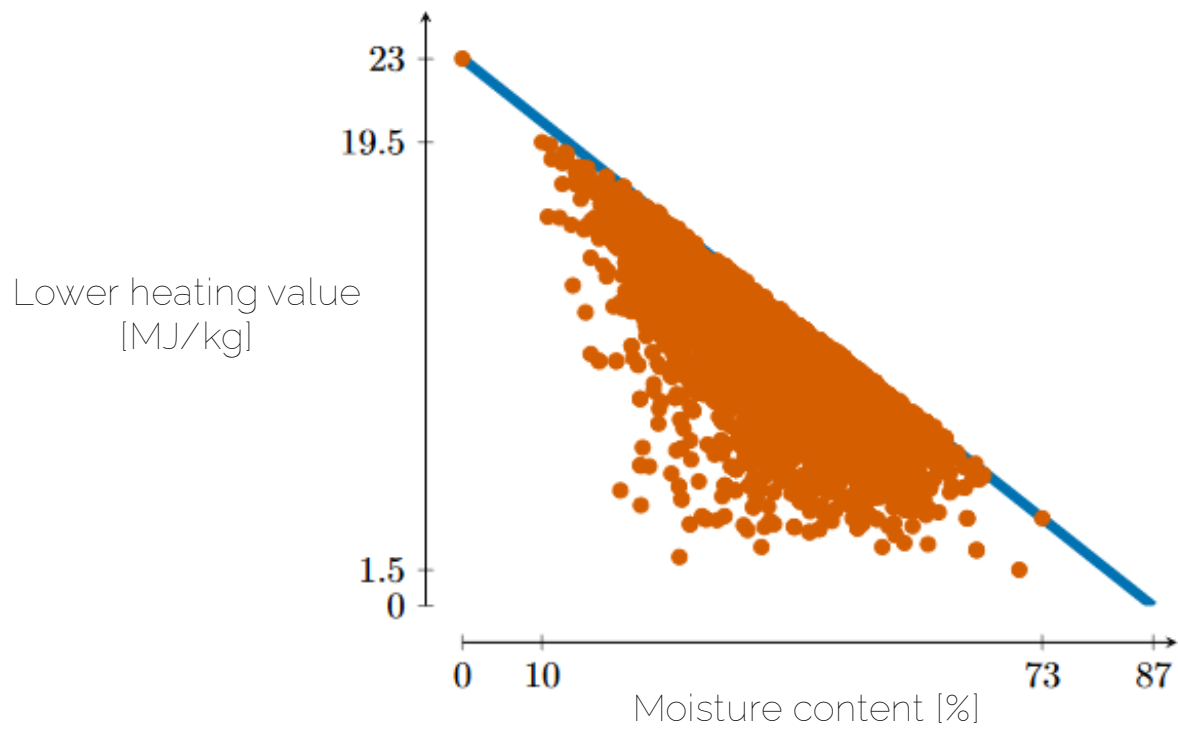

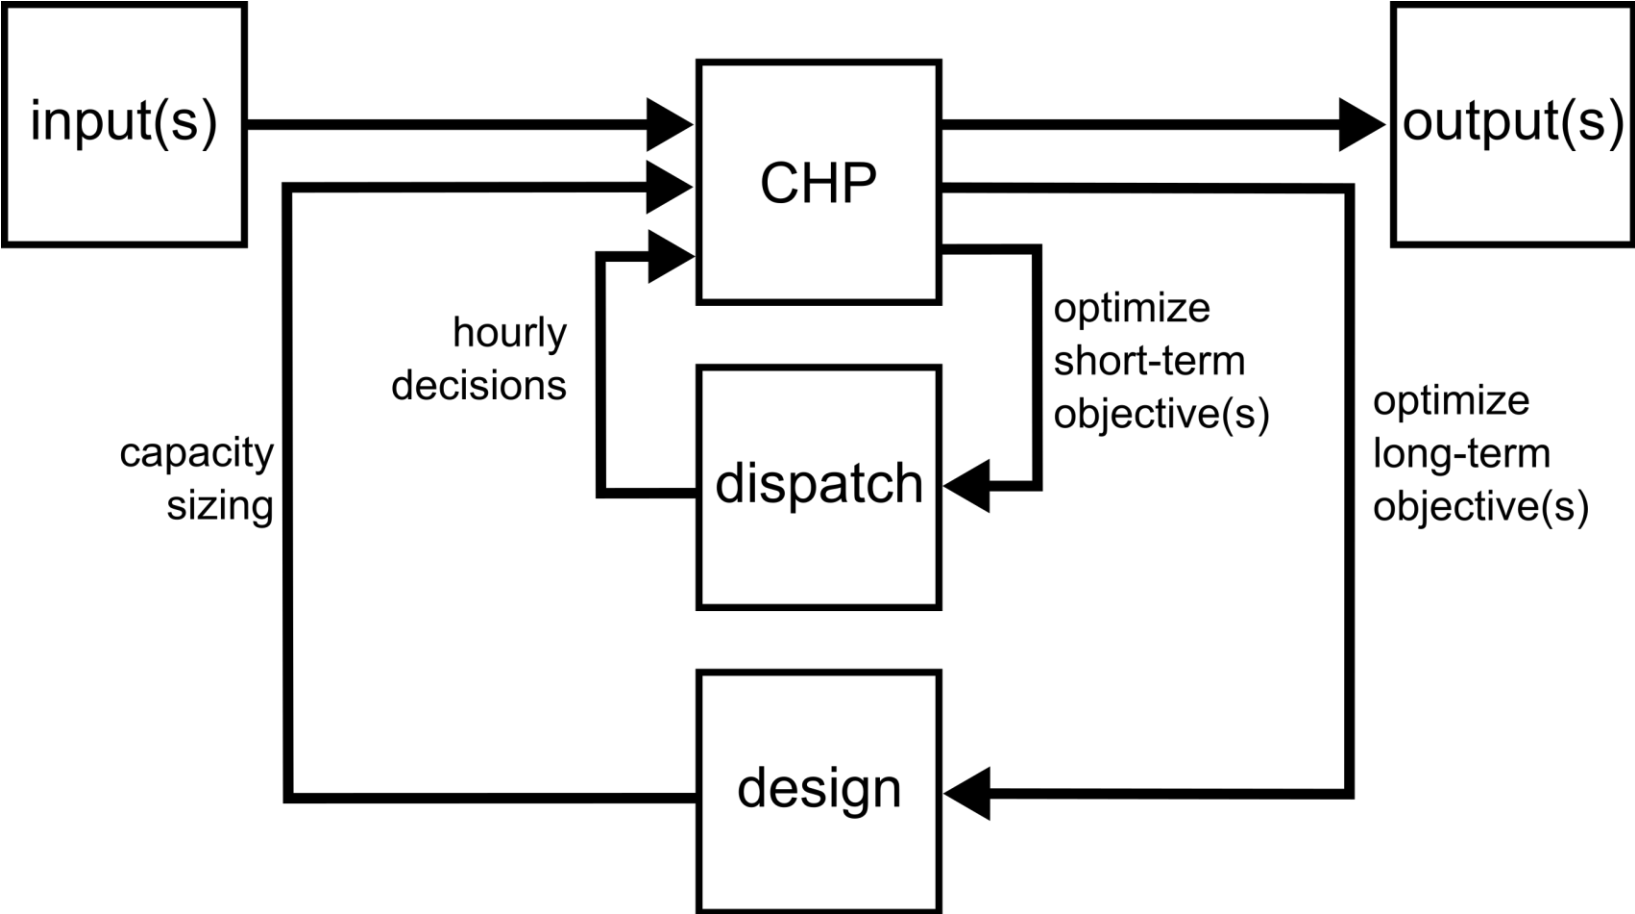

$$\dot{Q}_{\text{boiler}} = a P^2 + b P + c H^2 + d * H + e * P * H$$

A two-step optimization approach optimizes daily optimization while minimizing investment

Searching for key performance indicators for measuring flexibility

Searching for key performance indicators for measuring flexibility

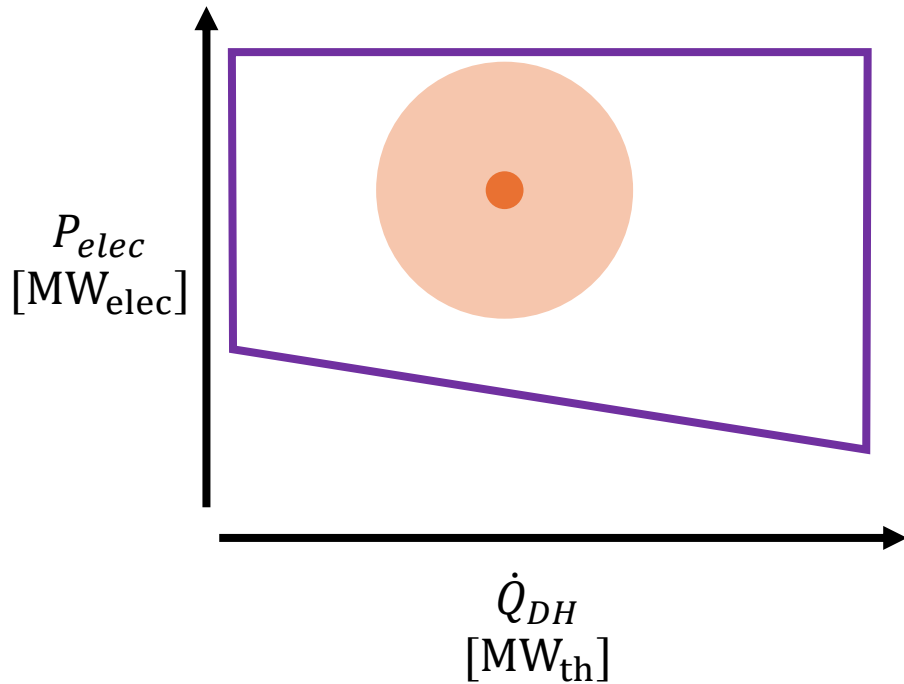

Searching for key performance indicators
for measuring flexibility

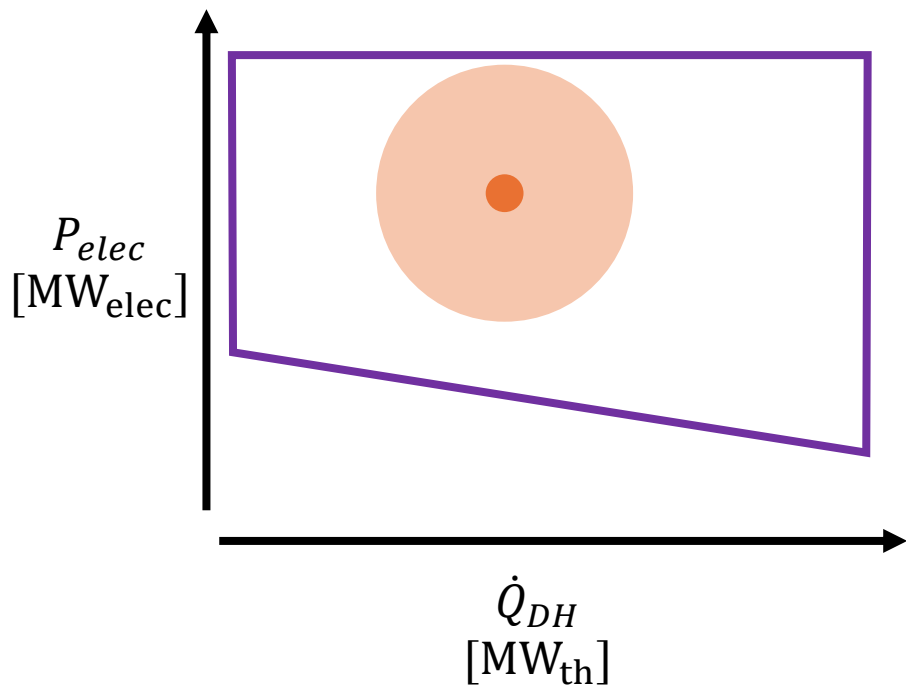

Flexibility index (FI) provides this measure

$$FI(t) = \frac{P_{up,max}(t+1) - P_{down,max}(t+1)}{P_{max}(\dot{Q}) - P_{min}(\dot{Q})}$$

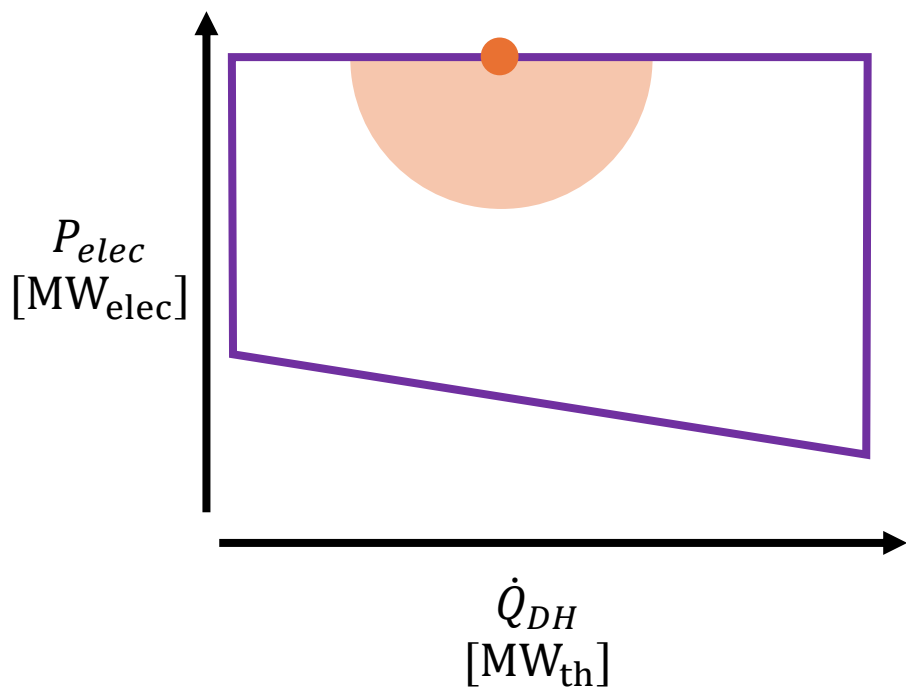

$$FI(t) = \frac{P_{up,max}(t+1) - P_{down,max}(t+1)}{P_{max}(\dot{Q}) - P_{min}(\dot{Q})}$$

$$FI(t) = \frac{1 - 0.6}{1 - 0.5} = 0.8$$

$$FI(t) = \frac{P_{up,max}(t+1) - P_{down,max}(t+1)}{P_{max}(\dot{Q}) - P_{min}(\dot{Q})}$$

$$FI(t) = \frac{1 - 0.8}{1 - 0.5} = 0.4$$

Other option is splitting the flexibility index

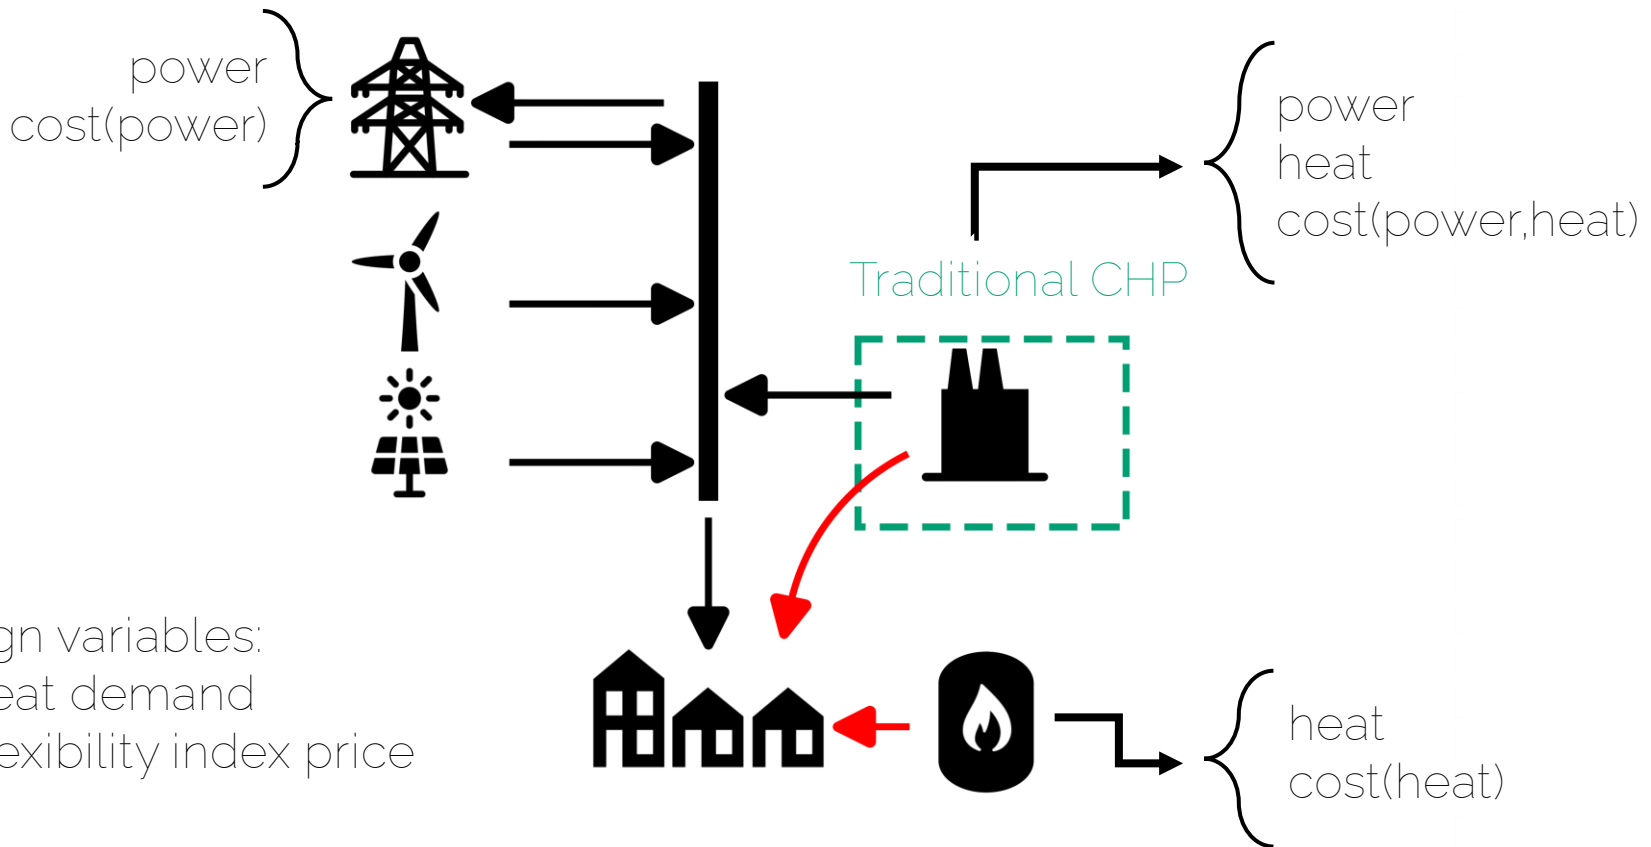

$$FI_{up}(t) = \frac{P_{up,max}(t+1) - P(t)}{P_{max}(\dot{Q}) - P(t)}$$

$$FI_{down}(t) = \frac{P(t) - P_{down,max}(t+1)}{P(t) - P_{min}(\dot{Q})}$$

The genetic algorithm adapts the capacities to find a design which optimizes the objectives

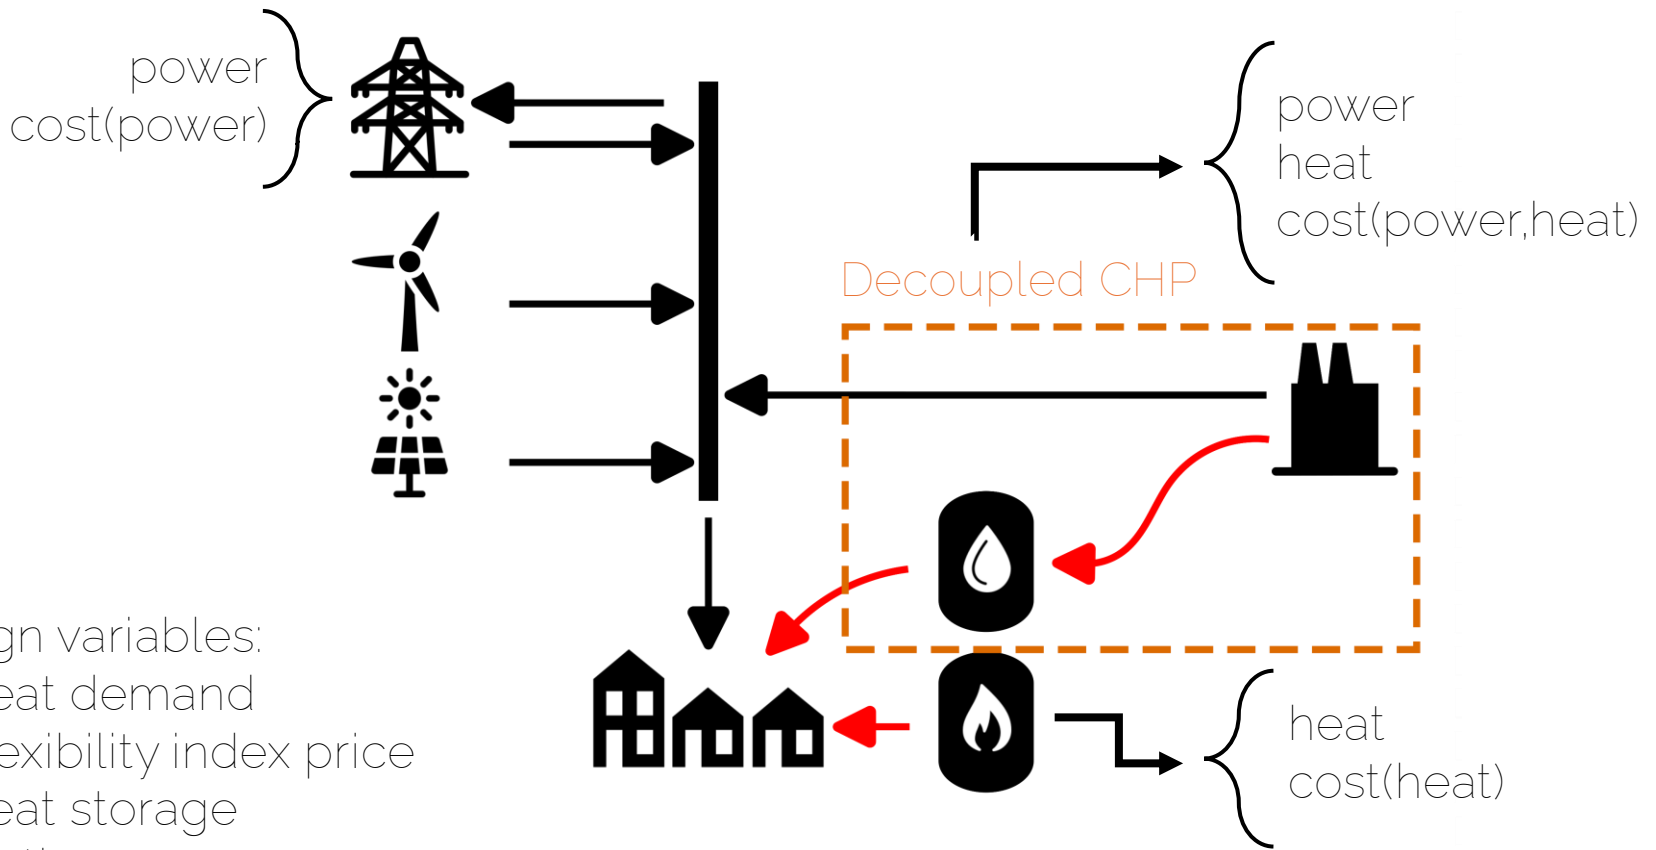

Design variables:

- Heat demand
- Flexibility index price

Objectives:

- maximize revenue CHP
- maximize flexibility index

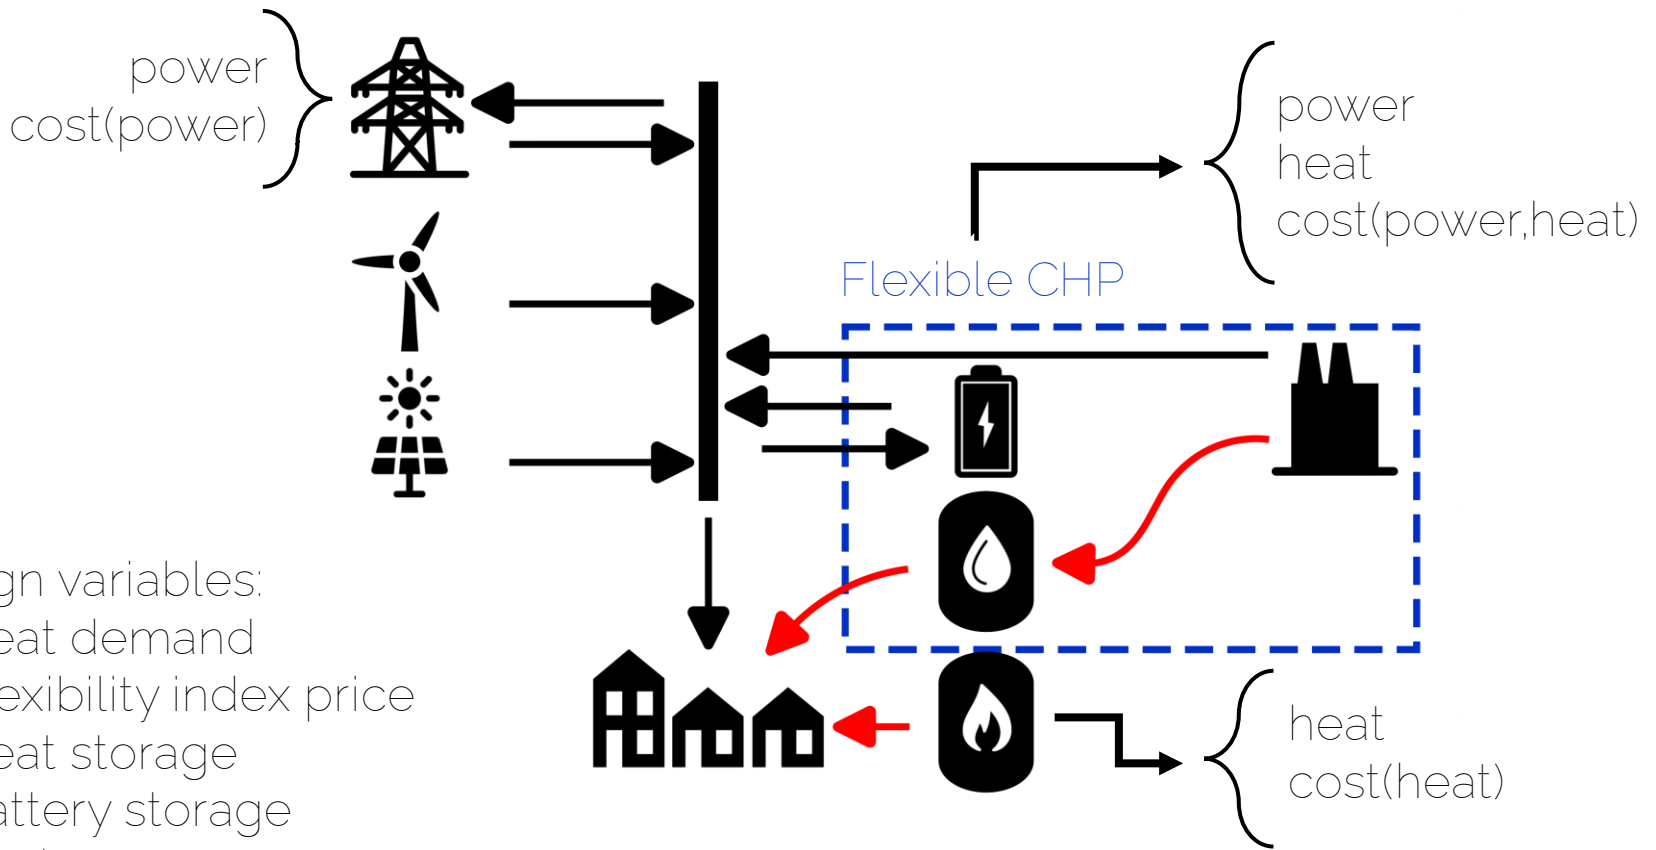

Design variables:

- Heat demand
- Flexibility index price
- Heat storage

Objectives:

- maximize revenue CHP
- maximize flexibility index

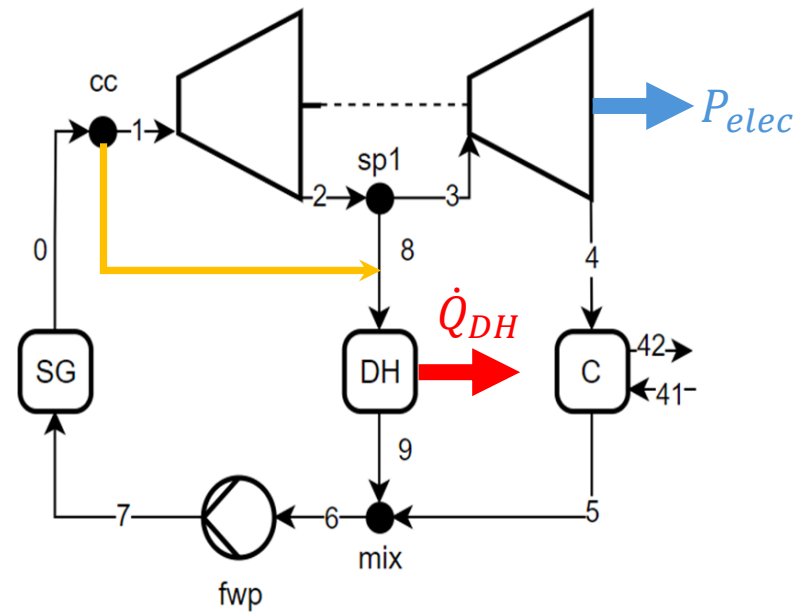

Design variables:

- Heat demand
- Flexibility index price
- Heat storage
- Battery storage

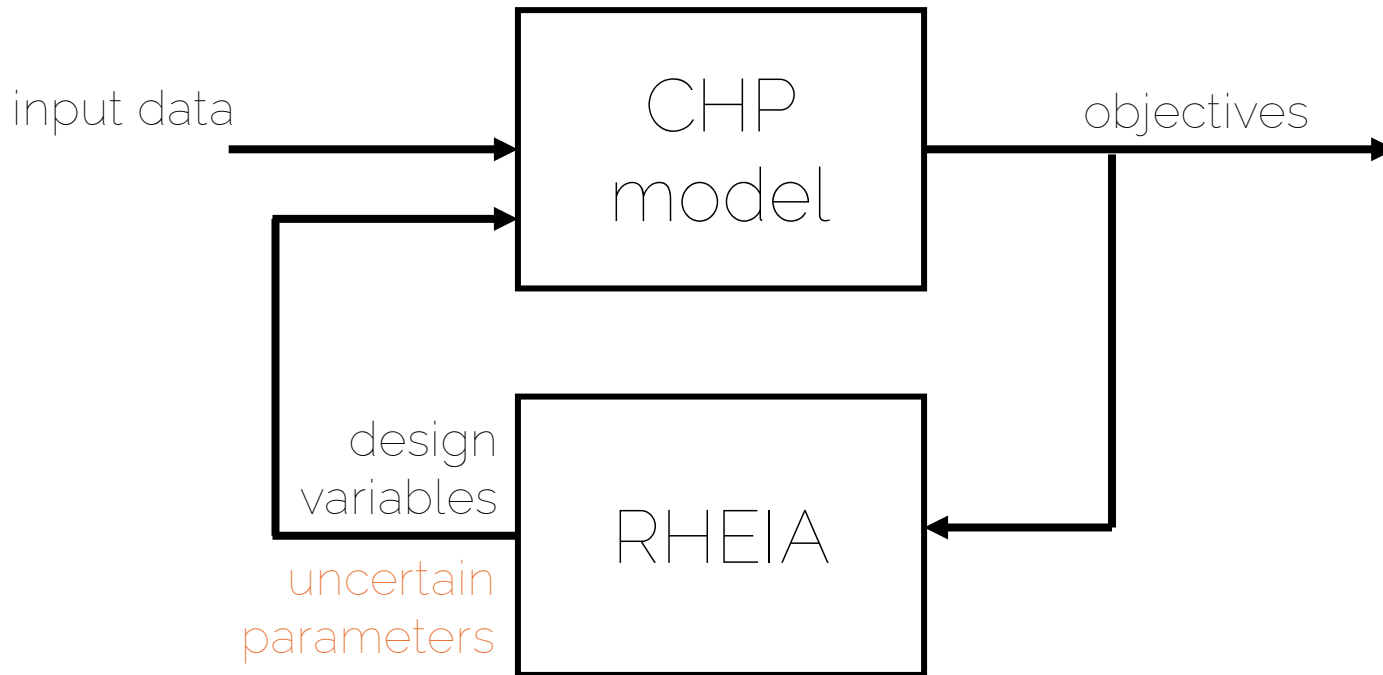

Objectives:

- maximize revenue CHP
- maximize flexibility index

In the future, CHP adaptations will be included to improve revenue and flexibility

The genetic algorithm adapts the capacities to find an optimal design **under uncertainties**

Conclusions

- an uncertain biomass and waste potential in the future in Belgium
- The performance of CHP plant is modelled
- Revenue and flexibility index will be optimized
- Additional components and uncertainties will be included
